Python type
system basics

Type
restrictions

Introduction

- Is everything an integer number?
- Yes and no

Everything is an integer number

- For the CPU everything is a string of bits
- So yes, everything is (*almost*^a) an integer number
- Complex data structures like a GUI, a 3D model, a picture, etc. are made up of collections of numbers

^aalso floats are recognized by the CPU

Everything is an integer number

- Low-level languages expose this view
- Everything is encoded with numbers
- It can become quite messy

Not everything is an integer number

- For the programmer, there exist different kinds of values
- So common and useful that Python offers them out of the box
- Even if the CPU does not manipulate them directly

Kinds of values

- Python has a **type system**
- Variables have different **data types**, often shortened to **types**
 - Integer numbers
 - Rational (floating point) numbers
 - Boolean truth values
 - Strings of text

Integers

- Numbers without dot^a
- 0, 100, -500, ...

^acomma in Dutch

Integers

- Typical arithmetic operations on numbers (**not in Python 3**)
- $3 + 5 = 8$, $5 / 2 = 2$, $40 * 5 = 200$, ...

Floating points

- Numbers with dot^a
- 0.0, 2.5, 10.0e3, 3.1e-5, -.1e-5, ...

^acomma in Dutch

The scientific notation

- 0.000001 is annoying to write
- we can write `1.e-5` instead
- the sign `e-N` means *add N zeros right after the dot*

The scientific notation

- 1000000.0 is annoying to write
- we can write 1.e6 instead
- the sign eN means *add N zeros right before the dot*

Floating points

- Typical arithmetic operations on numbers
- $5.0 / 2.0 = ?$, $10.0e3 / 0.1 = ?$, $3.1e-5 + 1.0e5 = ?$, ...
- **Can you guess the results?**

Floating points

- Typical arithmetic operations on numbers
- $5.0 / 2.0 = ?$, $10.0e3 / 0.1 = ?$, $3.1e-5 + 1.0e5 = ?$, ...
- **Can you guess the results?**
- $5.0 / 2.0 = 2.5$, $10.0e3 / 0.1 = 10.0e4$, $3.1e-5 + 1.0e5 = 100000.000031$, ...

Conversion to and from floating point

- Integers can be converted to floating points with `float(n)`
- Floating points can be converted to integers with `int(n)`

Conversion to and from floating point

- `int(2.5) = ?`, `float(3) = ?`
- **Can you guess the results?**

Conversion to and from floating point

- `int(2.5) = ?`, `float(3) = ?`
- **Can you guess the results?**
- `int(2.5) = 2`, `float(3) = 3.0`

Types

Dr. Giuseppe
Maggiore

Introduction

Python type system basics

Type restrictions

Conversion to and from floating point

- Floating points can lose their decimal values
- They stay float's, but always end in .0
- `math.floor(n)` truncates the tail
- `math.ceil(n)` fills the tail and increases to the next unit

Types

Dr. Giuseppe
Maggiore

Introduction

Python type
system basics

Type
restrictions

Conversion to and from floating point

- `floor(2.5) = ?`, `ceil(2.5) = ?`
- **Can you guess the results?**

Conversion to and from floating point

- `floor(2.5) = ?`, `ceil(2.5) = ?`
- **Can you guess the results?**
- `floor(2.5) = 2.0`, `ceil(2.5) = 3.0`

Conversion to and from floating point

- Some conversions happen automatically
- Python operations try to preserve information
- $5 / 2.0 = 2.5$, and 5 is converted to 5.0 right before the division

Python 3 integer division

- The new version of Python has a new integer division: it always converts to float
- It is **very different** from most other programming languages
- $5 / 2 = 2.5$

Types

Dr. Giuseppe
Maggiore

Introduction

Python type system basics

Type restrictions

Python 3 integer division

- Traditional integer division is now //
- $5 // 2 = 2$

Types

Dr. Giuseppe

Python type
system basics

Type
restrictions

Boolean values

- Truth values
- True, False

Types

Dr. Giuseppe
Maggiore

Introduction

Python type
system basics

Type
restrictions

Boolean values

- Logical operators on truth values
 - & for and
 - | for or
 - not

Types

Boolean values

- Comparison operators on numeric values
 - >
 - <
 - ==
 - >=
 - <=

Types

Dr. Giuseppe
Maggiore

Introduction

Python type system basics

Type restrictions

Boolean values

- $5.0 > 2.0 = ?$, $(3 > 4) \mid (5 == (3 + 2)) = ?$,
True & False = ?, ...
- **Can you guess the results?**

Boolean values

- `5.0 > 2.0 = ?`, `(3 > 4) | (5 == (3 + 2)) = ?`,
`True & False = ?`, ...
- **Can you guess the results?**
- `5.0 > 2.0 = true`, `(3 > 4) | (5 == (3 + 2)) =`
`False`, `True & False = False`, ...

String values

- Text
- "Hello!", "Hello world!", "", ...

String values

- String literals are sequences of characters, on a single line, between double " or single ' quotes
- Some characters do not fit this description
- We need special markings for such characters
- These special markings are called *escape characters*

Types

Dr. Giuseppe
Maggiore

Introduction

Python type
system basics

Type
restrictions

String values

- `\'` for single quote
- `\"` for double quote
- `\a` for ASCII Bell (BEL)
- `\b` for ASCII Backspace (BS)
- `\f` for ASCII Formfeed (FF)
- `\n` for ASCII Linefeed (LF)
- `\r` for ASCII Carriage Return (CR)
- `\t` for ASCII Horizontal Tab (TAB)
- `\v` for ASCII Vertical Tab (VT)
- `\\` for newline

String values

- `"Hello\n world"` is a string on two lines
- `"Hello\n world\n of Python"` is a string on three lines
- ...

String values

- The most common operator is string concatenation
- `"Hello" + "\n" + "world" + "\n" + "on" + "\n" + "different" + "\n" + "lines"`

Operations, types, and restrictions

- Not all operations are allowed on all possible variable types
 - Some operations are allowed (integer addition)
 - Some operations are not allowed (string division)
 - Some operations change meaning (addition of integers versus concatenation of strings)

Operations, types, and restrictions

- Examples of allowed operators
 - Addition, subtraction, division, multiplication, etc. between numbers
 - Concatenation between strings
 - Multiplication of strings and integers
 - Arithmetic comparison between numbers or strings
 - Conjunction, disjunction, negation^a between booleans
 - Treating integers as booleans (1=True, 0=False)
 - Treating strings as booleans (anything else=True, ""=False)

^aand, or, not

Operations, types, and restrictions

- Examples of not-allowed operators
 - Most arithmetic operations on strings and non-strings
("Hello" + True)
 - Most boolean operations on strings and non-strings
("Hello" & True)

Not-allowed operators generate *type errors*

```
Traceback (most recent call last):  
  File "C:\Users\Giuseppe\Desktop\DEV_I\samples\  
    DEV_I_samples.py", line 8, in <module>  
      print("Oh_noes,_a_bug!" + 4)  
TypeError: cannot concatenate 'str' and 'int'  
objects
```

Operations, types, and restrictions

- Variables may change type in Python
- An integer variable becomes later on a string variable
- This is allowed, but dangerous
- A variable should never lose reasonable meaning
- Many type errors stem from *changes in meaning*, connected with *changes in type* of a variable

Introduction

Python type
system basics

Type
restrictions

Instructions

- Split into four groups.
- Use the data types you saw in this lesson to model a soldier in a Python program.
- Example: Health, Team colour, ...
- Compile and run the program.
- Draw on a sheet what he soldier should look like.
- Hand over the code to another group and make them draw the soldier.
- If the pictures are the same then you have succeeded, otherwise rewrite your code.

system basics

Type
restrictions

Hand-in

- Write your names and student numbers on your sheets
- Hand them in
- *They may be used at your oral check* in the form of questions such as “how would you rewrite this after the course”
